Notes:

1. Benign and Uncertain Behaviour tumours have limited potential for proliferation or spreading, while invasive or malignant tumours are more likely to proliferate. The WHO grade of a Brain or Central Nervous System (CNS) tumour is an indication of proliferation potential, with Grade I tumours having low proliferation potential, increasing to Grade IV having high proliferation potential.
2. The age-standardised rate for an area is the number of tumour diagnoses (Incidence) or deaths (Mortality) per 100,000 population that would occur in a 'standard reference population' (the 'European Standard Population' has been used), if that standard population had the same age distribution (based on 5 year age-bands) as the population of interest.
3. Relative survival is the probability of survival of a person with cancer when compared with people of the same age and sex in a comparable population (in these analyses the whole population of England is used).
4. All survival analyses are for patients of all ages (0-99 years old) at diagnosis.
